Constructions of Almost Optimal Resilient Boolean Functions on Large Even Number of Variables

WeiGuo Zhang, Member, IEEE, and GuoZhen Xiao

Abstract—In this paper, a technique on constructing nonlinear resilient Boolean functions is described. By using several sets of disjoint spectra functions on a small number of variables, an almost optimal resilient function on a large even number of variables can be constructed. It is shown that given any \( m \), one can construct infinitely many \( n \)-variable \((n\text{ even})\), \( m \)-resilient functions with nonlinearity \( > 2^{n-1} - 2^{n/2} \). A large class of highly nonlinear resilient functions which were not known are obtained. Then one method to optimize the degree of the constructed functions is proposed. Last, an improved version of the main construction is given.

Index Terms—Algebraic degree, Boolean function, disjoint spectra functions, nonlinearity, resiliency, stream cipher.

I. INTRODUCTION

B OOLEAN functions are used as nonlinear combiners or nonlinear filters in certain models of stream cipher systems. In the design of cryptographic Boolean functions, there is a need to consider a multiple number of criteria simultaneously. The widely accepted criteria are balancedness, high nonlinearity, high algebraic degree, and correlation immortality of high order (for balanced functions, correlation immunity is referred to as resiliency).

By an \((n, m, d, N_f)\) function we mean an \( n \)-variable, \( m \)-resilient (order of resiliency \( m \)) Boolean function \( f \) with algebraic degree \( d \) and nonlinearity \( N_f \).

Unfortunately, all the criteria above cannot be maximized together. For \( n \) even, the most notable example is perhaps bent functions [19]. Achieving optimal nonlinearity \( 2^{n-1} - 2^{n/2-1} \), bent functions permit to resist linear attacks in the best possible way. But they are improper for cryptographic use because they are neither balanced nor correlation-immune and their algebraic degrees are not more than \( n/2 \). When concerning the order of resiliency, Siegenthaler [28] and Xiao [31] proved that \( d \leq n - m - 1 \) for \( m \)-resilient Boolean functions. Such a function, reaching this bound, is called degree-optimized.

For the reasons above, it is more important to construct those degree-optimized resilient Boolean functions which have almost optimal (large but not optimal) nonlinearity, say between \( 2^{n-1} - 2^{n/2} \) and \( 2^{n-1} - 2^{n/2-1} \), when \( n \) is even. This is also what we do in this paper.

We now give a summary of earlier results that are related to our work.

1) To obtain nonlinear resilient functions, a modification of the Maiorana–McFarland (M-M) construction of bent functions (cf. [5]) by concatenating the small affine functions was first employed by Camion et al. [1] and later studied in [27], [3], [21]. The nonlinearity of \( n \)-variable M-M resilient functions cannot exceed \( 2^{n-1} - 2^{n/2} \). The M-M technique in general does not generate degree-optimized functions and the M-M functions are potentially cryptographically weak [2], [9].

2) An interesting extension of the M-M technique has been made by Carlet [2], where the concatenation of affine functions is replaced by concatenation of quadratic functions. In general, these constructed functions cannot be degree-optimized, and the other parameters, such as nonlinearity and resiliency, are not better than those of the M-M functions.

3) Pasalic [17] presented a revised version of the M-M technique to obtain degree-optimized resilient functions. The modification is simple and smart but the nonlinearity value of the constructed functions is at most \( 2^{n-1} - 2^{[n/2]} \).

4) Sarkar and Maitra [21] indicated that for each order of resiliency \( m \), it is possible to find an even positive integer \( n \) to construct an \((n, m, n-m-1, N_f)\) function \( f \) with \( N_f > 2^{n-1} - 2^{n/2} \). They showed that for even \( n \geq 12 \), the nonlinearity of \( 1 \)-resilient functions with maximum possible algebraic degree \( n-2 \) can reach \( 2^{n-1} - 2^{n/2-1} - 2^{n/2-2} - 2^{n/4-2} - 4 \). It was further improved due to the method proposed by Maitra and Pasalic [12]. Thanks to the existence of the \((8,1,6,116)\) functions, an \((n, 1, n-2, N_f)\) function \( f \) with \( N_f = 2^{n-1} - 2^{n/2-1} - 2^{n/2-2} - 4 \) could be obtained, where \( n \geq 10 \).

5) Seberry et al. [26] and Dobbertin [6] independently presented constructions of highly nonlinear balanced Boolean functions by modifying the M-M bent functions. To obtain an \( n \)-variable balanced function, they concatenated \( 2^{n/2} - 1 \) nonconstant distinct \( n/2 \)-variable linear functions and one \( n/2 \)-variable modified M-M class highly nonlinear balanced Boolean function which can be constructed in a recursive manner. These constructed functions attain the best known nonlinearity for \( n \)-variable \((n \text{ even})\) balanced functions.

6) To obtain \( m \)-resilient functions with nonlinearity \( > 2^{n-1} - 2^{n/2-1} - 2^{n/2-2} \) for \( n \) even and \( n \geq 14 \), Maitra and Pasalic [11] applied the concatenation of \( 2^{n/2} - 2^d \) distinct functions.
linear \( m \)-resilient functions on \( n/2 \) variables together with a highly nonlinear resilient function on \( n/2 + k \) variables. Moreover, they have provided a generalized construction method for \( m \)-resilient functions with nonlinearity \( 2^{n-1} - 2^{n/2-1} - 2^{n/2-3} - 2^{n/2-4} \) for all \( n \geq 8m + 6 \). For sufficiently large \( n \), it is possible to get such functions with nonlinearity \( \approx 2^{n-1} - 2^{n/2-1} - 2^{n/2-2} \). And it is the upper bound on maximum possible nonlinearity under their construction method.

7) Computer search techniques have played an important role in the design of cryptographic Boolean functions in the last ten years [14], [16], [15], [4]. For a small number of variables, Boolean functions with good cryptographic parameters can be found by using heuristic search techniques [12], [20], [8]. However, search techniques cannot be used for functions with a large number of variables at present.

8) During the past decade, the most instructive results on the design of cryptographic Boolean functions were centered on finding small functions with desirable cryptographic properties. When it comes to constructing large functions, people used recursive constructions [29], [30], [7] besides the M-M construction and its revised (extended) versions. With the rapid development of integrated circuit technique, Boolean functions with large number of variables can be easily implemented in hardware [22].

In this paper we propose a technique to construct high non-linear resilient Boolean functions on large even number of variables \((n \geq 12)\). We obtain a large class of resilient Boolean functions with a nonlinearity higher than that attainable by any previously known construction method.

The organization of this paper is as follows. In Section II, the basic concepts and notions are presented. In Section III, we present a method to construct a set of “disjoint spectra functions” by using a class of “partially linear functions”. Our main construction is given in Section IV. A method for constructing resilient functions on large even number of input variables is proposed. We show that all the constructed functions are almost optimal. In Section V, the degrees of the constructed functions are optimized. In Section VI, an improved version of the main construction is given. Finally, Section VII concludes the paper with an open problem.

II. PRELIMINARY

To avoid confusion with the additions of integers in \( \mathbb{R} \), denoted by + and \( \sum \), we denote the additions over \( \mathbb{F}_2 \) by \( \oplus \) and \( \bigoplus \). For simplicity, we denote by + the addition of vectors of \( \mathbb{F}_2^n \). A Boolean function of \( n \) variables is a function from \( \mathbb{F}_2^n \) into \( \mathbb{F}_2 \), and we denote by \( \mathcal{B}_n \) the set of all Boolean functions of \( n \) variables. A Boolean function \( f(X_n) \in \mathcal{B}_n \), where \( X_n = (x_1, \cdots, x_n) \in \mathbb{F}_2^n \), is generally represented by its algebraic normal form (ANF)

\[
f(X_n) = \bigoplus_{u \in \mathbb{F}_2^k} \lambda_u \left( \prod_{i=1}^{n} x_i^{u_i} \right) \quad (1)
\]

where \( \lambda_u \in \mathbb{F}_2 \) and \( u = (u_1, \ldots, u_n) \). The algebraic degree of \( f(X_n) \), denoted by \( \deg(f) \), is the maximal value of \( \text{wt}(u) \) such that \( \lambda_u \neq 0 \), where \( \text{wt}(u) \) denotes the Hamming weight of \( u \). A Boolean function with \( \deg(f) \leq 1 \) is said to be affine. In particular, an affine function with constant term equal to zero is called a linear function. Any linear function on \( \mathbb{F}_2^n \) is denoted by

\[
\omega \cdot X_n = \omega_1 x_1 + \cdots + \omega_n x_n
\]

where \( \omega = (\omega_1, \ldots, \omega_n) \in \mathbb{F}_2^n \). The Walsh spectrum of \( f \in \mathcal{B}_n \) in point \( \omega \) is denoted by \( W_f(\omega) \) and calculated by

\[
W_f(\omega) = \sum_{X_n \in \mathbb{F}_2^n} (-1)^{f(X_n) \cdot \omega \cdot X_n}, \quad (2)
\]

\( f \in \mathcal{B}_n \) is said to be balanced if its output column in the truth table contains equal number of 0’s and 1’s (i.e., \( W_f(0) = 0 \)).

In [31], a spectral characterization of resilient functions has been presented.

Lemma 1: An \( n \)-variable Boolean function is \( m \)-resilient if and only if its Walsh transform satisfies

\[
W_f(\omega) = 0, \text{ for } 0 \leq \text{wt}(\omega) \leq m, \omega \in \mathbb{F}_2^n. \quad (3)
\]

The Hamming distance between two \( n \)-variable Boolean functions \( f \) and \( \rho \) is denoted by

\[
d(f, \rho) = \{ X_n \in \mathbb{F}_2^n : f(X_n) \neq \rho(X_n) \}.
\]

The set of all affine functions on \( \mathbb{F}_2^n \) is denoted by \( A(n) \). The nonlinearity of a Boolean function \( f \in \mathcal{B}_n \) is its distance to the set of all affine functions and is defined as

\[
N_f = \min_{\rho \in A(n)} (d(f, \rho)).
\]

In term of Walsh spectra, the nonlinearity of \( f \) is given by [13]

\[
N_f = 2^{n-1} - 2 \cdot \max_{\omega \in \mathbb{F}_2^n} |W_f(\omega)|. \quad (4)
\]

Parseval’s equation [10] states that

\[
\sum_{\omega \in \mathbb{F}_2^n} (W_f(\omega))^2 = 2^{2n} \quad (5)
\]

and implies that

\[
N_f \leq 2^{n-1} - 2^{n/2-1}.
\]

The equality occurs if and only if \( f \in \mathcal{B}_n \) are bent functions, where \( n \) is even.

Bent functions can be constructed by the M-M method. The original M-M functions are defined as follows: for any positive integers \( p, q \) such that \( n = p + q \), an M-M function is a function \( f \in \mathcal{B}_n \) defined by

\[
f(Y_p, X_p) = \phi(Y_q) \cdot X_p \oplus \pi(Y_q), \quad X_p \in \mathbb{F}_2^p, Y_q \in \mathbb{F}_2^q \quad (6)
\]

where \( \phi \) is any mapping from \( \mathbb{F}_2^p \) to \( \mathbb{F}_2^p \) and \( \pi \in \mathcal{B}_q \). When \( n \) is even, \( p = q = n/2 \), and \( \phi \) is injective, the M-M functions are
bent. Certain choices of \( \phi \) can easily yield bent functions with degree \( n/2 \). For the case of \( n = 2 \), \( f \in B_2 \) is bent if and only if \( \deg(f) = 2 \).

The M-M construction is in essence a concatenation of affine functions. The following definition shows a more general approach to obtain a “large” Boolean function by concatenating the truth tables of any small Boolean functions.

**Definition 1:** Let \( Y_q \in F_2^q \), \( X_p \in F_2^p \), and \( p, q \) be positive numbers with \( p + q = n \). \( f \in B_n \) is called a concatenation of the functions in the set \( G = \{ g_b \mid b \in F_2^q \} \subset B_p \) if

\[
f(Y_q, X_p) = \bigoplus_{b \in F_2^q} Y_q^b \cdot g_b(X_p)
\]

(7)

where the notation \( Y_q^b \) is defined by

\[
Y_q^b = \begin{cases} 
1, & \text{if } Y_q = b \\
0, & \text{if } Y_q \neq b
\end{cases}
\]

(8)

Theorem 2 in [28] allows us to verify that the following lemma is true.

**Lemma 2:** With the same notation as in Definition 1, if all the functions in \( G \) are \( m \)-resilient functions, then \( f \) is an \( m \)-resilient function.

From now on, we will focus on highly nonlinear resilient Boolean functions with an even number of variables in the following sense.

**Definition 2:** Let \( n \geq 4 \) be even. \( f \in B_n \) is said to be almost optimal if

\[
2^{n-1} - 2^{n/2} \leq N_f < 2^{n-1} - 2^{n/2-1}.
\]

(9)

### III. A LARGE SET OF DISJOINT SPECTRA FUNCTIONS

Disjoint spectra functions will play an important role in constructing almost optimal resilient functions in this paper.

**Definition 3:** A set of Boolean functions \( \{ g_1, g_2, \ldots, g_e \} \subset B_p \) such that for any \( \alpha \in F_2^p \)

\[
W_{g_i}(\alpha) \cdot W_{g_j}(\alpha) = 0, \quad 1 \leq i < j \leq e
\]

(10)

is called a set of disjoint spectra functions.

The idea that two Boolean functions with disjoint spectra can be used to construct highly nonlinear resilient functions was clearly mentioned in [18], and it was also used in [29], [7], [12]. In this section, we provide a simple construction method for a large set of disjoint spectra functions by using a set of “partially linear” functions.

As a family of special resilient functions, partially linear functions were firstly considered by Siegenthaler [28]. Here is the definition of such functions.

**Definition 4:** Let \( t \) be a positive integer and \( \{ i_1, \ldots, i_t \} \subset \{ i_{t+1}, \ldots, i_p \} = \{ 1, \ldots, p \} \). Let \( X_p = (x_1, \ldots, x_p) \in F_2^p \), \( X'_t = (x_{i_1}, \ldots, x_{i_t}) \in F_2^t \) and \( X''_{p-t} = (x_{i_{t+1}}, \ldots, x_p) \in F_2^{p-t} \). For any \( c \in F_2^t \), \( g_c \in B_p \) is called a \( t \)-th-order partially linear function if

\[
g_c(X_p) = c \cdot X'_t \oplus h_c(X''_{p-t})
\]

(11)

where \( h_c \in B_{p-t} \).

Now we use partially linear functions to construct a set of disjoint spectra functions.

**Lemma 3:** With the same notation as in Definition 4, a set of \( t \)-th-order partially linear functions

\[
T = \{ g_c(X_p) = c \cdot X'_t \oplus h_c(X''_{p-t}) \mid c \in F_2^t \}
\]

(12)

is a set of disjoint spectra functions.

**Proof:** Let \( \alpha = (\delta, \theta) \in F_2^p \), where \( \delta \in F_2^t \) and \( \theta \in F_2^{p-t} \). For any \( g_c \in T \),

\[
W_{g_c}(\alpha) = \sum_{X_p \in F_2^p} (-1)^{\cdot \delta \cdot h_c(X''_{p-t}) \oplus \theta \cdot X_p}
\]

\[
= \sum_{X_p \in F_2^p} (-1)^{\cdot (c+\delta) \cdot h_c(X''_{p-t}) \oplus \theta \cdot X_p}
\]

\[
= \sum_{X'_t \in F_2^t} \sum_{X''_{p-t} \in F_2^{p-t}} (-1)^{\cdot (c+\delta) \cdot X'_t} \cdot W_{h_c}(\theta)
\]

(13)

We have

\[
W_{g_c}(\alpha) = \begin{cases} 
0, & \text{if } c \neq \delta \\
2^t \cdot W_{h_c}(\theta), & \text{if } c = \delta
\end{cases}
\]

(14)

For any \( g_{c'} \in T \), \( c' \neq c \), we have

\[
W_{g_c}(\alpha) \cdot W_{g_{c'}}(\alpha) = 0.
\]

According to Definition 3, \( T \) is a set of disjoint spectra functions.

Disjoint spectra functions (partially linear functions) will be used as the “components” to construct almost optimal resilient Boolean functions in this paper.

**Open Problem:** Construct a large set of disjoint spectra functions which are not (linearly equivalent to) partially linear functions.

### IV. MAIN CONSTRUCTION

This section presents a method for constructing resilient Boolean functions with very high nonlinearity. The algebraic degrees of the functions are also given.

**Construction 1:** Let \( n \geq 12 \) be an even number, \( m \) be a positive number, and \( (a_1, \ldots, a_s) \in F_2^s \) such that

\[
\sum_{j=m+1}^{n/2} \binom{n/2}{j} + \sum_{k=1}^{s} a_k \cdot \sum_{j=m+1}^{n/2-2k} \binom{n/2-2k}{j} \geq 2^{n/2}
\]

(15)

where \( s = \lfloor (n-2m-2)/4 \rfloor \). Let \( X_{n/2} = (x_1, \ldots, x_{n/2}) \in F_2^{n/2} \), \( X'_t = (x_1, \ldots, x_t) \in F_2^t \), and \( X''_{2k} = (x_{t+1}, \ldots, x_{n/2}) \in F_2^{2k} \) with \( t + 2k = n/2 \). Let

\[
\Gamma_0 = \{ c \cdot X_{n/2} \mid c \in F_2^{n/2}, \ wt(c) > m \}.
\]

(16)
For $1 \leq k \leq s$, let $H_k$ be a nonempty set of $2k$-variable bent functions with algebraic degree $\max(k, 2)$ and
\begin{equation}
\Gamma_k = \{c \cdot X_1 \oplus h_c(X_{2n}) | c \in F_{2}^t, \text{wt}(c) > m\}
\end{equation}
where $h_c \in H_k$. Set
\begin{equation}
\Gamma = \bigcup_{k=0}^{s} \Gamma_k.
\end{equation}
Denote by $\phi$ any injective mapping from $F_{2}^{n/2}$ to $\Gamma$. Then for $(Y_{n/2}, X_{n/2}) \in F_{2}^{n/2} \times F_{2}^{n/2}$ we construct the function $f \in B_n$ as follows:
\begin{equation}
f(Y_{n/2}, X_{n/2}) = \bigoplus_{b \in F_{2}^{n/2}} Y_{n/2}^b \cdot \phi(b).
\end{equation}
**Remark 1:**
1. For Inequality (15) holds, we have
\begin{equation}
|\Gamma| = \sum_{k=0}^{s} |\Gamma_k| \geq 2^{n/2}.
\end{equation}
Due to this we can find an injective mapping $\phi$.
2. All the functions in $\Gamma$ are partially linear functions and each $\Gamma_k$ is a set of disjoint spectra functions.

**Theorem 1:** Let $f \in F_{2}^n$ be as in Construction 1. Then $f$ is an almost optimal $(n, m, d, N_f)$ function with
\begin{equation}
N_f \geq 2^{n-1} - 2^{n/2-1} - \sum_{k=1}^{s} (a_k \cdot 2^{n/2-k-1})
\end{equation}
and
\begin{equation}
d = n/2 + \max\{2, \max\{|a_k|, k = 1, 2, \ldots, s\}\}.
\end{equation}

**Proof:** For any $(\beta, \alpha) \in F_{2}^{n/2} \times F_{2}^{n/2}$ we have
\begin{equation}
W_f(\beta, \alpha) = \sum_{(Y_{n/2}, X_{n/2}) \in F_{2}^{n/2}} (-1)^{f(Y_{n/2}, X_{n/2})} = \sum_{b \in F_{2}^{n/2}} (-1)^{\beta b} \sum_{X_{n/2} \in F_{2}^{n/2}} (-1)^{g_b(X_{n/2})} = \sum_{b \in F_{2}^{n/2}} (-1)^{\beta b} W_{g_b}(\alpha) = \sum_{k=0}^{s} \sum_{\phi(b) \in \Gamma_k} (-1)^{\beta b} W_{g_b}(\alpha)
\end{equation}
Let $0 \leq k \leq s$. Any $g_b \in \Gamma_k$ is a partially linear function. From (14), we have
\begin{equation}
W_{g_b}(\alpha) \in \{0, \pm2^{n/2-k}\}.
\end{equation}
Let
\begin{equation}
A_k = \Gamma_k \cap \left\{\phi(b) \mid b \in F_{2}^{n/2}\right\}.
\end{equation}
Since (15) holds, there exists an injective mapping $\phi$ such that
\begin{equation}
\sum_{k=1}^{s} |A_k| = \sum_{i=1}^{m} \binom{n/2}{i},
\end{equation}
From Lemma 3, $\Gamma_k$ is a set of disjoint spectra functions. Noting (10), if $A_k \neq \emptyset$, then we have
\begin{equation}
\sum_{\phi(b) \in \Gamma_k} (-1)^{\beta b} W_{g_b}(\alpha) \in \{0, \pm2^{n/2-k}\},
\end{equation}
If $A_k = \emptyset$, then we have
\begin{equation}
\sum_{\phi(b) \in \Gamma_k} (-1)^{\beta b} W_{g_b}(\alpha) = 0.
\end{equation}
Combining (23), (26), and (27), we have
\begin{equation}
|W_f(\beta, \alpha)| \leq 2^{n/2} + \sum_{k=1}^{s} a_k \cdot 2^{n/2-k}
\end{equation}
where
\begin{equation}
a_k = \begin{cases} 0, & \text{if } A_k = \emptyset, \\ 1, & \text{if } A_k \neq \emptyset. \end{cases}
\end{equation}
From (4), Inequality (21) holds. From Definition 2, $f$ is almost optimal.

Note that the algebraic degree of any function in $\Gamma_1$ is 2. Hence, when
\begin{equation}
\max\{|a_k|, k = 1, 2, \ldots, s\} = 1
\end{equation}
d $\leq (m/2) + 2$ where the equality holds if and only if $|A_1|$ is odd. Note that the algebraic degree of any bent functions of $F_{2}^{2k}$ can reach $k$ when $k \geq 2$. So $d$ can reach $(n/2) + k'$ when $k' \geq 2$ and $|A_k|$ is odd, where
\begin{equation}
k' = \max\{|a_k|, k \neq 0, k = 1, 2, \ldots, s\}.
\end{equation}
Any $g_b \in \Gamma$, $b \in F_{2}^{n/2}$, is an $m$-resilient function, where $g_b(X_{n/2}) = \phi(b)$. From Lemma 2, $f$ is an $m$-resilient function since it is a concatenation of $m$-resilient functions.

**Remark 2:**
1. The nonlinearity of the resilient functions constructed above is always strictly greater than $2^{n-1} - 2^{n/2}$. For reasonable fixed $n$ and $m$, the nonlinearity of the constructed functions is always greater than that of the known ones except some functions on small even number of variables.
2. Let $m$ be the maximum number such that Inequality (15) holds. Roughly speaking, $m/n$ tends to $1/4$.

**Example 1:** It is possible to construct a $(16, 1, 10, 2^{15} - 2^7 - 2^5)$ function.
Note that $s = \lfloor (n - 2m - 2)/4 \rfloor = 3$. For $1 \leq k \leq 3$, let $X_{8-2k} = (x_1, \ldots, x_{8-2k}) \in F_{2}^{8-2k}$ and $X_{8-2k} = (x_{8-2k+1}, \ldots, x_8) \in F_{2}^{8}$. Let $X_8 = (X_{8-2k}^*, X_{8-2k}) \in F_{2}^{n/2}$. We construct four sets of disjoint spectra functions as follows:
\begin{equation}
\Gamma_0 = \{c \cdot X_8 \mid \text{wt}(c) > 1, c \in F_{2}^{n/2}\},
\end{equation}
For $1 \leq k \leq 3$
\begin{equation}
\Gamma_k = \{c \cdot X_{8-2k} \oplus h_c(X_{8-2k}) \mid \text{wt}(c) > 1, c \in F_{2}^{n/2-2k}\}.
\end{equation}
where $h_c \in H_k$. We have

$$|\Gamma_k| = \sum_{i=2}^{32} \binom{8 - 2k}{i}, \quad 0 \leq k \leq 3.$$ 

Notice that

$$|\Gamma_0| + |\Gamma_2| = 258 > 2^8$$

it is possible to establish an injective mapping $\phi$ from $F_2^n$ to $F_2$, where $\mathcal{R} = \Gamma_0 \cup \Gamma_2$. Then for $(Y_8, X_8) \in F_2^n \times F_2^k$ we construct the function $f \in B_{16}$ as follows:

$$f(Y_8, X_8) = \bigoplus_{b \in F_2^k} Y_8^b \cdot \phi(b).$$

From (28), for any $(\beta, \alpha) \in F_2^n \times F_2^k$, we have

$$\max_{(\beta, \alpha) \in F_2^n} |W_{f}(\beta, \alpha)| \leq \sum_{k=0}^{3} \sum_{g \in \Gamma_k} |W_{g}(\alpha)|$$

$$= \sum_{k=0}^{3} \max_{\alpha \in F_2^n} |W_{g}(\alpha)| = 2^8 + 2^6.$$

By (4), we have

$$N_f \geq 2^{15} - 2^7 - 2^5.$$ 

Note that the partially linear function in $\Gamma_2$ can be denoted by $g = c \cdot X_4' \oplus h_c(X_4')$ where $h_c$ is a bent function on $F_2^2$. Since the algebraic degree of $h_c(X_4')$ can reach $2$, $\deg(g)$ can reach $8 + 2 = 10$. So it is possible to obtain a $(16, 1, 10, 2^{15} - 2^7 - 2^5)$ function.

V. DEGREE OPTIMIZATION

Let

$$\{i_1, \ldots, i_{m+1}\} \cup \{i_{m+2}, \ldots, i_{n/2}\} = \{1, \ldots, n/2\}.$$ 

The algebraic degree of any $(n, m, d, N_f)$ function $f$ obtained in Construction 1 can be optimized by adding a monomial $x_{i_{m+2}} \cdots x_{i_{n/2}}$ to one function $g \in \Gamma'$ with $\phi^{-1}(g) \neq \emptyset$, where $g$ can be denoted by

$$g = x_{i_1} \oplus \cdots \oplus x_{i_{m+1}} \oplus h_c(x_{i_{m+2}} \cdots x_{i_{n/2}}).$$

(32)

It is not difficult to prove that $N' \geq \{N_f, N_f - 2^{m+1}\}$, where $N_f'$ is the nonlinearity of the degree-optimized function $f'$. To optimize the algebraic degree of $f$ and ensure that $N_f = N_f'$, we below propose an idea to construct a set of disjoint spectra functions $\Gamma'_0$ including a nonlinear function $f' = g + x_{i_{m+2}} \cdots x_{i_{n/2}}$.

Construction 2: Let $n \geq 12$ be an even number, $m$ a positive number, and $(a_1, \ldots, a_s) \in F_2^3$ such that

$$\left( \sum_{j=m+1}^{n/2} \binom{n/2}{j} - 2^{n/2-m-1} + 1 \right) + \sum_{k=1}^{s} \binom{n/2 - 2k}{j} \geq 2^{n/2} \tag{33}$$

where $s = [(n - 2m - 2)/4]$. Let

$$S = \{c | c = (c_1 \ldots c_{n/2}) \in F_2^{n/2}, \quad \text{wt}(c) > m, (c_1, \ldots, c_{m+1}) = (1 \ldots 1) \}.$$ 

(34)

Let

$$g'(X_{n/2}) = c' \cdot X_{n/2} \oplus x_{i_{m+2}} \cdots x_{i_{n/2}} \tag{35}$$

where $c' \in S$. For $1 \leq k \leq s$, $\Gamma_k$ is defined as in Construction 1. And we modify the $\Gamma_0$ in Construction 1 as follows:

$$\Gamma'_0 = \{g'(X_{n/2})\} \cup \{c \cdot X_{n/2} | c \in F_2^{n/2}, \text{wt}(c) > m, c \notin S\}.$$ 

(36)

Set

$$\Gamma' = \Gamma'_0 \cup \Gamma_1 \cup \cdots \cup \Gamma_s.$$ 

(37)

Denote by $\phi'$ any injective mapping from $F_2^{n/2}$ to $\Gamma'$ such that $\phi^{-1}(g', c') \neq \emptyset$. The function $f' \in B_n$ is constructed as follows:

$$f'(Y_{n/2}, X_{n/2}) = \bigoplus_{b \in F_2^{n/2}} Y_{n/2}^b \cdot \phi'(b).$$

(38)

Theorem 2: Note that $f' \in F_2^{n/2}$ is proposed by Construction 2. Then $f'$ is an almost optimal $(n, m, n - m - 1, N_f)$ functions with

$$N_f' \geq 2^{n-1} - 2^{n-2} - \sum_{k=1}^{s} a_k \cdot 2^{n/2-k-1}.$$ 

(39)

Proof: $f'$ is an $m$-resilient function since it is a concatenation of $m$-resilient functions.

Let $g(X_{n/2}) = \phi'(b) \in \Gamma'$, $b \in F_2^{n/2}$. From the proof of Theorem 1, for any $(\beta, \alpha) \in F_2^{n/2} \times F_2^{n/2}$, we have

$$W_f(\beta, \alpha) = \sum_{b \in F_2^{n/2}} (-1)^{\beta \cdot b} W_{g}(\alpha)$$

$$+ \sum_{k=1}^{s} \sum_{b \in F_2^{n/2}} (-1)^{\beta \cdot b} W_{g}(\alpha).$$

(40)
Let $\ell' = (\ell'_1, \ldots, \ell'_{n/2}) \in \mathbb{F}_2^{n/2}$ and $\alpha = (\alpha_1, \ldots, \alpha_{n/2}) \in \mathbb{F}_2^{n/2}$. We have

$$W_{\ell'}(\alpha) = \sum_{X_{n/2} \in \mathbb{F}_2^{n/2}} (-1)^{(c' + \alpha) \cdot X_{n/2} \oplus x_{m+2} \cdots x_{n/2}}$$

$$= \left\{ \begin{array}{ll} 2^{n/2} - 2^{m+2}, & \text{if } \alpha \neq \ell' \\
 \pm 2^{m+2}, & \text{if } \alpha \neq \ell' \text{ and } \theta = \delta, \\
 0, & \text{if } \alpha \neq \ell' \text{ and } \theta \neq \delta \end{array} \right. \quad (41)$$

where $\delta = (\ell'_1, \ldots, \ell'_{m+1})$ and $\theta = (\alpha_1, \ldots, \alpha_{m+1})$. Let $g_b(X_{n/2}) = \varphi'(b) \in \Gamma'_b, b \in \mathbb{F}_2^{n/2}$. When $g_b \in \Gamma'_0$ and $g_b = c' \cdot X_{n/2} \neq g'$, we have

$$W_{g_b}(\alpha) = \left\{ \begin{array}{ll} 0, & \text{if } \alpha \neq c' \cdot X_{n/2} \\
 2^{n/2}, & \text{if } \alpha = c' \cdot X_{n/2} \end{array} \right. \quad (42)$$

From (36), if $\alpha \neq \ell'$ and $(\alpha_1, \ldots, \alpha_{m+1}) = (1 \cdots 1)$, then $\alpha \neq c$. Obviously, $\Gamma'_0$ is a set of disjoint spectra functions. So we have

$$\sum_{\varphi'(b) \in \Gamma'_b} (-1)^{34} W_{g_b}(\alpha)$$

$$\in \{0, \pm 2^{m+2}, \pm (2^{n/2} - 2^{m+2}), \pm 2^{n/2}\} \quad (43)$$

Let $A_k = \Gamma_k \cap \{\varphi'(b) | b \in \mathbb{F}_2^{n/2}\}$. Similarly to the proof of Theorem 1, for any $(\beta, \alpha) \in \mathbb{F}_2^n$, we have

$$|W_{f'}(\beta, \alpha)| \leq 2^{n/2} + \sum_{k=1}^8 a_k \cdot 2^{n/2-k}$$

where

$$a_k = \left\{ \begin{array}{ll} 0, & \text{if } A_k = \emptyset \\
 1, & \text{if } A_k \neq \emptyset \end{array} \right.$$  

From (3), Inequality (39) holds and $f'$ is obviously almost optimal. For the existence of $g', \deg(f') = n - m - 1$. \qed

**Remark 3:**
1. Apparently, the idea above to obtain degree-optimized resilient functions is firstly considered by Pasalic [17].
2. A long list of input instances and the corresponding cryptographic parameters can be found in Tables I and II. In Table II, the entries with "*" represent the functions that can not be degree optimized via Construction 2 on the premise of the fact $N_f = N_{f'}$.

VI. IMPROVED VERSION OF THE MAIN CONSTRUCTION

Both constant functions and balanced Boolean functions are regarded as 0-resilient functions. The Boolean functions that are neither balanced nor correlation-immune are regarded as $(\alpha 1)$-resilient functions (e.g., bent functions).

**Lemma 4:** With the same notation as in the Definition 4, if $h_c$ is a $v$-resilient function, then $g_b$ is a $(\text{wt}(c) + v)$-resilient function.

**Proof:** Let $\alpha \in \mathbb{F}_2^n$ and $l = c \cdot X_l'$. It is not difficult to deduce that $W_{h_c}(\alpha) = W_{f'(\alpha_1, \ldots, \alpha_k)} W_{g_b}(\alpha_{k+1}, \ldots, \alpha_{n/2})$. When $\text{wt}(\alpha_1, \ldots, \alpha_k) < \text{wt}(c)$, $W_{h_c}(\alpha_{k+1}, \ldots, \alpha_{n/2}) = 0$. From Lemma 1, for $h_c$ is a $v$-resilient function, we have

$$W_{h_c}(\alpha_{k+1}, \ldots, \alpha_{n/2}) = 0; \quad \text{for } \text{wt}(\alpha_{k+1}, \ldots, \alpha_{n/2}) \leq v.$$  

Obviously, $W_{g_b}(\alpha) = 0$ when $\text{wt}(\alpha) \leq \text{wt}(c) + v$. From Lemma 1, $g_b$ is a $(\text{wt}(c) + v)$-resilient function. \qed

**Construction 3:** Let $n \geq 12$ be an even number, $m$ be a positive number, $c_k$ be a nonnegative number with $0 \leq c_k \leq k$, and let $k \in \mathbb{F}_2(k = 1, \ldots, [n/4])$ such that

$$\sum_{i=m+1}^{n/2} \binom{n/2}{i} + \sum_{k=m+1}^{\lfloor n/4 \rfloor} a_k \cdot \sum_{j=m+1}^{n/2-2k} \binom{n/2 - 2k}{j} \geq 2^n/2.$$  

Let

$$X_{n/2} = (x_1, \ldots, x_{n/2}) \in \mathbb{F}_2^{n/2}$$

$$X_{l'} = (x_1, \ldots, x_l) \in \mathbb{F}_2^l$$

and

$$X_{2k} = (x_{l+1}, \ldots, x_{n/2}) \in \mathbb{F}_2^{2k}$$

where $t + 2k = n/2$. Let

$$\Omega_0 = \{c \cdot X_{n/2} | c \in \mathbb{F}_2^{n/2}, \text{wt}(c) > m\}.$$  

(45)

For $1 \leq k \leq \lfloor n/4 \rfloor$ and $0 \leq c_k \leq m - 1$, let $R_k$ be a nonempty set of $(2^{k+1}, c_k - 1 - m, N_{h_b}, N_{\varphi^{-1}(g_b)})$ functions with high nonlinearity and

$$\Omega_k = \{c \cdot X_{l'} \oplus h_b(X_{2k}) | c \in \mathbb{F}_2^l, \text{wt}(c) > m - c_k\}$$

(46)

where $h_c \in R_k$. Set

$$\Omega = \bigcup_{k=0}^{\lfloor n/4 \rfloor} \Omega_k.$$  

(47)

Denote by $\varphi$ any injective mapping from $\mathbb{F}_2^{n/2}$ to $\Omega$ such that there exists an $(n/2, m, n/2 - m - 1, N_{f'}, f')$ function $g_b \in \Omega$ with $\varphi^{-1}(g_b) \neq \emptyset$. We construct the function $f \in B_n$ as follows:

$$f(Y_{n/2}, X_{n/2}) = \bigoplus_{b \in \mathbb{F}_2^{n/2}} Y_{n/2}^b \cdot \varphi(b).$$  

(48)

**Theorem 3:** If $f \in B_n$ is proposed by Construction 3, then $f$ is an almost optimal $(n, m, n - m - 1, N_f)$ function with

$$N_f \geq 2^{n-1} - 2^{n/2-1} - \sum_{k=1}^{\lfloor n/4 \rfloor} (a_k \cdot 2^{n/2-2k} \cdot (2^{2k-1} - N_{h_b})).$$

(49)

**Proof:** For any $(\beta, \alpha) \in \mathbb{F}_2^{n/2} \times \mathbb{F}_2^{n/2}$, we have

$$W_{f}(\beta, \alpha) = \sum_{k=0}^{n/2} \sum_{b \in \mathbb{F}_2^{n/2}} (-1)^{34} W_{g_b}(\alpha)$$

</table>

Note: The table continues with more entries not shown in the image.
Let
\[ A_k = \Omega_k \cap \{ \phi(b) | b \in \mathbb{F}_2^{n/2} \}. \]  
(51)

Note that each \( \Omega_k \) is a set of disjoint spectra functions. Similarly to the proof of Theorem 1, we obtain
\[ |W_f(\beta, \alpha)| \leq 2^{n/2} + \sum_{k=1}^{s} a_k \cdot 2^{n/2-2k} \cdot (2^{2k} - 2N_h_k) \]  
(52)

where
\[ a_k = \begin{cases} 0, & \text{if } A_k = \emptyset \\ 1, & \text{if } A_k \neq \emptyset \end{cases}. \]

From (3), Inequality (49) holds.

From Lemma 4, all the functions in \( \Omega \) are \( m \)-resilient functions. Due to Lemma 2, \( f \) is an \( m \)-resilient function. For the existence of a degree-optimized function \( g_h \in \Omega \) with \( \varphi^{-1}(g_h) \neq \emptyset \), we have \( \deg(f) = n - m - 1 \). □

Fixing \( n \) and \( m \), we can also obtain lots of degree-optimized resilient functions whose nonlinearity are better than that of functions constructed by Construction 1. See the following example.

**Example 2:** It is possible to construct a \((28,1,26,2^{27} - 2^{13} - 2^8 - 2^6)\) function. Let
\[ \Omega_0 = \{ c \cdot X'_1 | c \in \mathbb{F}_2^{14}, wt(c) \geq 2 \} \]
and
\[ \Omega = \{ c \cdot X'_4 \oplus h_c(X'_{10}) | c \in \mathbb{F}_2^4, h_c \in \mathcal{R}_5 \} \]
where \( \mathcal{R}_5 \) is a nonempty set of nonlinear \((10,1,8,492)\) functions [8]. Note that \( |\Omega_0| = 16336, |\Omega_5| = 16 \). For \( 16336 + 16 > 2^{14} \), it is possible to select many \( 14 \)-variable \( 1 \)-resilient functions from \( \Omega_0 \cup \Omega_5 \). We concatenate these functions and obtain a \((28,1,26,2^{27} - 2^{13} - 2^8 - 2^6)\) function.

Similarly, one can obtain the following resilient functions:
\[(36,5,32,2^{35} - 2^{17} - 2^{13}), (42,5,36,2^{41} - 2^{29} - 2^{27} - 2^{25}), (86,4,81,2^{85} - 2^{42} - 2^{29} - 2^{27} - 2^{26} - 2^{25}), (66,10,55,2^{65} - 2^{32} - 2^{29} - 2^{28} - 2^{27} - 2^{26} - 2^{25}), \]
etc.

**VII. CONCLUSION AND AN OPEN PROBLEM**

In this paper, we described a technique for constructing resilient functions with good nonlinearity on large even number variables. As a consequence, we obtained general constructions of functions which were not known earlier.

Sarkar and Maitra [23] have shown that the nonlinearity of any \((n,m,n - m - 1, N_f)\) function \((m \leq n - 2)\) is divisible by \(2^{n+1}\). And they have deduced the following result: If \( n \) is even, and \( m \leq n/2 - 2 \), then \( N_f \leq 2^{n-1} - 2^{n/2-1} - 2^{n+1} \). But we suppose that this upper bound could be improved. So we propose an open problem as follows.

Does there exist \( n \)-variable \((n \text{ even}), m \)-resilient \((m \geq 0)\) functions with nonlinearity \(\geq 2^{n-1} - 2^{n/2-1} - 2^{n/4} + m + 1\)? If there does, how to construct these functions?

**Conjecture:** Let \( n \geq 12 \) be even and \( m \leq n/2 - 2 \). For any \((n,m,n, N_f)\) function, the following inequality always holds:
\[ N_f \leq 2^{n-1} - 2^{n/2-1} - 2^{n/4} + m + 1. \]  
(53)

**ACKNOWLEDGMENT**

The authors would like to thank the anonymous reviewers and the Associate Editor K. Martin for their comments that improved the technical and the editorial quality of this paper. The first author is also grateful to Prof. CunSheng Ding and Dr. BaoCang Wang for critical reading of the manuscript and to Chao Lv for his assistance in designing a program to find the examples in the tables.
